===== This is a small program which will correct an input signal, a digital signal for example. It works very well for Hifi and Audio systems, including listening room compensation. Just read all about it in the help files to understand how it works. The program will generate a correction filter and will fit it in a file with 3 parameters. The input signal must be sent via the serial port (USB). The serial port is the same used by the Digital Output Test Chart. In fact, all inputs are tested before to generate the correction filter. The 3 parameters are: 1. The frequency of correction, in hz. 2. The gain of the correction filter. 3. The number of FIR filter taps used by the filter. The program can run in 3 different ways: 1. When no correction is required (default setting). 2. If the provided frequency is within the range of the correction filter. 3. If the provided frequency is outside the range of the correction filter. The program can generate the following types of filters, which will cover 99% of HiFi and Audio applications: - Low Pass - High Pass - Band Pass - Band Stop - Band Reject - Comb Filter - Comb and Reject Filter - Comb and Band Reject Filter - Comb and Band Stop Filter Each of these filters has a different gain. The gain is controlled with a simple slider. The setting is linear, so the gain is the same on the whole frequency range. The number of taps of the filter is also controlled with a slider, which is linear. The increase of the number of taps will be very fast until some point, and slower afterwards. The frequency of the correction filter can be set in the Hz with a simple slider. The program can use 3 different sampling rates, in hz: 1. 44.1 2. 48 3. 88.2 The program is simple and can be used to generate a lot of FIR filters. The program requires a few seconds to generate the filters for an input signal of 16 Kbps (1.1 Mbit) or 32 Kbps (2.2 Mbit) samples/sec, with 1 to 50 KHz

1. Record measurement values at user selected frequency: Keymacro allows recording of frequency response values using selected frequencies at a given speed and resolution. There are multiple options for recording the result including online, offline and fixed. If frequency resolution is selected as fast, the number of value recorded per second will increase, but the frequency response resolution will decrease. Therefore, select a resolution based on the desired frequency range. A: The recordings are done online, therefore the entire frequency response will be measured and recorded. B: The recordings are done offline, therefore the frequency response is recorded only when the samples are generated. After the run of recording, the sample is stored in the same location in the file as the measurements were done, which is commonly in a corresponding logbook. C: The recordings are done offline, therefore the frequency response is recorded only when the samples are generated. After the run of recording, the sample is stored in the same location in the file as the measurements were done, which is commonly in a corresponding logbook. When the frequency is changed, the recorded values are stored into different file locations, in order to save space. The results will be saved in a directory named after the selected frequency. 2. Generate correction filters for selected frequency resolution: In order to get the correction filters for a specific set of parameters, select the desired frequency, then select the frequency resolution, recording length and desired filter length. The number of samples recorded is selected. The measurement speed is selected. After that, you can edit the selected filter length, offset and pass-band frequency response, or the settings can be saved to the logbook, in order to use them again. 3. Test Filter Algorithm Accuracy: It's very important that the filter lengths are calculated with accurate values, because the filter length and the frequency have a significant impact on the quality of the filter generated. Keymacro can test filter length, filter band and offset, and it's possible to specify the desired filter length and band and the rest is calculated. These values are not the exact values as determined by the algorithm, but it will be calculated based on these values. The test results will be recorded in the logbook, and the results can be viewed afterwards. 4. Generate and calculate the offset filter: It's possible to generate and calculate the offsets for the filter. It will be calculated 1d6a3396d6

===== MouseTool is an application designed to control and measure parameters of audio systems and loudspeakers. It is both a versatile and powerful application that enables the user to perform many measurements. MouseTool can be used as a real time solution for waveform and spectrum measurement, and as a post-production application for room acoustics. MouseTool includes the following features: \* Room equalization; \* Delay compensation; \* Bandwidth and level limiting; \* Power equalization; \* A/B comparison  
MouseTool Includes: ===== MouseTool is free to try for 1 week. A limited demo version of MouseTool is also included. For further information, see MouseTool is distributed free of charge, and it is designed to be easy to use and understand. It is Open Source, and released under the GNU Public Licence (GPL). MouseTool is programmed in C#, and is cross platform (Windows, Linux, Mac). MouseTool Components: ===== \* A lightweight GUI (Graphical User Interface) that uses an RSS (XML) display that allows the user to select audio channel, sample rate, as well as apply any of the available correction filters. \* A very flexible system that allows any number of channel to be processed at any sample rate. \* A low delay (300 samples) system that allows the user to apply the correction in real time. \* A command line interface that allows the user to apply a large number of correction filters in real time. \* A logging and storing facility for logs and plots.  
\* MouseTool is released under GPL licence. MouseTool Examples: ===== MouseTool is a user-friendly application that allows the user to control and measure parameters of audio systems and loudspeakers. The GUI application is designed to work on any audio system that is connected to a computer, and it features a user friendly approach. The installation of the application is very simple, and doesn't require any external dependancies. MouseTool provides a free 14 day trial version. MouseTool Features: ===== \* Any number of input and output channels; \* Any number of input sample rates; \* Any number of output sample rates; \* A flexible filtering system that allows the user to apply any number of filter; \* A low delay (300 samples) system that allows the user to apply the correction in real time.

Digital Room Correction generates real time or offline FIR correction filters for HiFi and audio systems. The intended purpose of DRC is acoustic compensation of acoustic rooms, including listening room compensation. Supported RTAO versions: Windows 2000/XP/2003 Key features: - DRC will automatically generate the error filters depending on the type of the room. - Measurements are automatically determined on the fly - The user interface is very intuitive and resembles the Windows Calculator. - The user interface is very intuitive and resembles the Windows Calculator. - All measurements can be saved to allow for future analysis. - DRC can generate FIR filters of any order. - Convolver GUI (Graphical User Interface) which is for the convolver. - A graphical representation of the measured signal (room frequency response) which allows the user to select the best filter settings. - The user can easily select the best filter settings by adjusting the filters in the graphic representation of the measured signal. - DRC can generate the filters with any combination of sample rate, bandwidth, order, filter taps, window widths, and window type. How to use: The GUI for the convolver (graphical user interface) uses the same principle as the Windows calculator. - The user selects a filter setting by adjusting the values of the slider. - The GUI continuously updates the measurements of the FIR filters. - The user selects the best filter settings by choosing the optimal settings from the slider in the GUI. - The GUI allows the user to easily select the best filter settings. - The measurements for the convolver GUI are also saved and can be easily re-evaluated. - The GUI for DRC is entirely command line based. - DRC can be started with parameters saved from the convolver GUI. - The command line options are explained in the help file. Dependencies: If necessary, run the DRC installer with the command line option -p. This command line option tells the installer that the DRC program is not a pure command line application, but it is a combined GUI/command line application. Copyright (C) 2007-2016, G. Schindler Documentation: First and foremost, the executable files are no longer listed on the website. I don't want to keep these files on the web-page any more. The current information about the files can be found in the DRC readme file (current version: 0.9.2). I have also uploaded the manual to a separate web page. I have made a new wiki-page for a more detailed user's guide, which is included in the zip-file. \* The programs DRC (Digital Room Correction) and DRC-GUI (Digital Room Correction GUI) have been rewritten in F#. \* DRC and DRC-GUI are distributed as a single
